The vortex tube, also known as the Ranque-Hilsch vortex tube, is a mechanical device that separates a compressed gas into hot and cold streams. The gas emerging from the "hot" end can reach temperatures of 200 °C (392 °F), and the gas emerging from the "cold end" can reach $\hat{\hat{50}}^{\circ}\text{C}$ ($\hat{\hat{58}}^{\circ}\text{F}$). It has no moving parts.

In continuum mechanics, the vorticity is a pseudovector field that describes the local spinning motion of a continuum near some point (the tendency of something to rotate), as would be seen by an observer located at that point and traveling along with the flow.

1. Introduction In this paper we introduce a new method for the analysis of problems governed by partial differential equations such as, for example, solids, structures and fluids.

The main 1.8t FAQ is great and all...but it isn't kept updated with all the new, great stuff people do. The user who created it won't respond to PM's and the mods won't edit it either.

Most optimisation methods use an iterative procedure. The initial set X design variables, which in the context of aerodynamic optimisation this is referred to as the baseline configuration, and is updated until a minimum of $F(X)$ is identified or the optimisation process runs out of allocated time/iterations.
